Linked Data Benchmark Council

LDBC is a non-profit organization dedicated to establishing benchmarks, benchmark practices and benchmark results for graph data management SW.

LDBC's Social Network Benchmark is an industrial and academic initiative, formed by principal actors in the field of graph-like data management.

Choke points

- = a challenging aspect of query processing, a well-chosen difficulty
- Allows systematic benchmark design

CP-2.1: [QOPT] Rich join order optimization

TPC-H 2.3

This choke-point tests the ability of the query optimizer to find optimal join orders. A graph can be traversed in different ways. In the relational model, this is equivalent as different join orders. The execution time of these orders may differ by orders of magnitude. Therefore, finding an efficient join (traversal) order is important, which in general, requires enumeration of all the possibilities. The enumeration is complicated by operators that are not freely re-orderable like semi-, anti-, and outer-joins. Because of this difficulty most join enumeration algorithms do not enumerate all possible plans, and therefore can miss the optimal join order. Therefore, these chokepoint tests the ability of the query optimizer to find optimal join (traversal) orders.

Peter Boncz, Thomas Neumann, Orri Erling,
TPC-H Analyzed: Hidden Messages and Lessons Learned from an Influential Benchmark,
 TPCTC 2013

Q5: Top posters in a country

1. Find the *top 100* Forums by members in a given Country.
2. For each member of the *top 100* Forums, count their Posts in the *top 100* Forums.

Sparksee
SF10

CP-2.1 Rich join order optimization

Choke points: optimizations

- “Top- k pushdown” optimization
- New in LDBC (not covered in TPC-H choke points)

CP-1.3: [QOPT] Top- k pushdown

This choke-point tests the ability of the query optimizer to perform optimizations based on top- k selections. Many times queries demand for returning the top- k elements based on some property. Engines can exploit that once k results are obtained, extra restrictions in a selection can be added based on the properties of the k th element currently in the top- k , being more restrictive as the query advances, instead of sorting all elements and picking the highest k .

Queries

BI 2 BI 4 BI 5 BI 9 BI 16 BI 19 BI 22 IC 11

Q22: International dialog

For each p1-p2 pair, calculate score and get top pair (w/ tie-break)

+ 4 if p1 replied to p2

+ 1 if p2 replied to p1

+15 if p1 knows p2

+10 if p1 liked p2's msg

+ 1 if p2 liked p1's msg

= max. 31 in total

Q22: International dialog

+ 4 if p1 replied
+ 1 if p2 replied
+15 if p1 knows p2
+10 if p1 liked
+ 1 if p2 liked

= max. 31 in total

Avoiding full Cartesian product with Top- k pushdown:

Example #1:

- There are k pairs with maximum points (31).
- A pair cannot possibly achieve max. points $\rightarrow$ prune

Example #2:

- There are k pairs with at least 20 points.
- A pair fails the condition for 15 points $\rightarrow$ prune

Q16: Experts in social circle

1	messageCount	↓
2	tag.name	↑
3	person.id	↑

- SQL ✓
- SPARQL ✓
- Cypher: recently added ✓

Language choke points

New choke points to cover *language features*.

- CP-8.1: Complex patterns
- CP-8.2: Complex aggregations
- CP-8.3: Ranking-style queries
- CP-8.4: Query composition
- CP-8.5: Dates and times
- CP-8.6: Handling paths

Q25: Weighted interaction paths

1. Given two *Persons*, get all shortest paths on “knows” edges.

2. For each path, for each edge on the path, calculate a weight.

3. For each path, summarize weights.

4. Return paths, ordered by weights (desc).

(Q25 covers 15 CPs, incl. *all language-related ones* – its SQL impl. is ~2500 chars)

CP-8.6 Handling paths

1. Path unwinding: “higher-order” queries

Q25: weights based on additional pattern matching on path elements.

2. Matching semantics for paths

- Homomorphism-based (walks)
- Isomorphism-based
 - No-repeated-anything
 - No-repeated-edge semantics (trails)
 - No-repeated-node semantics (simple path)

Q16: “social circle” – persons connected by an edge-unique paths of $[x, y]$ hops

3. Regular path queries (RPQs)

R. Angles et al.,
Foundations of Modern Query Languages for Graph Databases,
 ACM Computing Surveys, 2017

CP-8.6 Handling paths

CP-8.6: [LANG] Handling paths

Handling paths as first-class citizens is one of the key distinguishing features of graph database systems [3]. Hence, additionally to reachability-style checks, a language should be able to perform *path unwinding* [1], i.e. express queries that operate on elements of a path such as calculating a score for each edge of a path. Also, some use cases specify uniqueness constraints on paths, e.g. that a certain path must not have repeated nodes (referred to as “walks” in graph theory) or not have repeated edges (“trails” in graph theory). Following the definitions of paper [1], *homomorphism-based semantics* (no constraints on repetitions) and multiple flavours of *isomorphism-based semantics* (no-repeated-node, no-repeated-edge, and no-repeated-anything).

Cypher. Cypher uses *no-repeated-edge matching semantics* (in return, this semantics is sometimes dubbed as *cyphermorphism*). Configurable matching semantics (e.g. `MATCH ALL WALKS`) were proposed in the open-Cypher language. RPQs are also proposed in the openCypher language as *path patterns*.

G-CORE. G-CORE treats paths as *first-order citizens*: its *path property graph data model* can store paths in the graph model itself. However, the language only supports shortest path semantics (for tractability reasons) and does not allow enumeration of all paths. G-CORE uses *homomorphism-based matching semantics*.

SPARQL. SPARQL uses *homomorphism-based matching semantics* and supports RPQs as *property paths*. Isomorphism-based matching semantics can be expressed by introducing custom filtering condition on predicates, e.g. `FILTER ( ?e1 != ?e2 )`.

Implementing the BI workload

High-level process

1. Generate data set
2. Implement loader
3. Implement driver adapter
4. Implement queries and validate

Validation

1. Generate validation set
2. Cross-validate for multiple SFs
3. Failure → fix issues and go to 2

Very time consuming process, but...

- after 2 validated tools – still bugs in *both* implementations
- after 3 validated tools – still ambiguities in the spec

Implementing the BI workload

Cross-validation for implementations

Cypher	Neo4j	25/25
SQL	PostgreSQL	25/25
Imperative	Sparksee	25/25
SPARQL	Stardog	24/25
PGQL	Oracle Labs PGX	10/25

In progress: Spark SQL

Roadmap

- 1. Help industry adoption** → get more benchmark results
- 2. Define updates on the graph.**
Necessitates complex dependency handling (SIGMOD'15 paper), and raises many design choices:
 - Affected types which nodes/edges? what distribution?
 - Nature of changes append-only vs. insert and delete
 - Granularity nodes/edges vs. attributes
 - Frequency of changes streaming vs. batch
- 3. Publish as a conference paper**
